

When pump is predicted recovering:

1. Do nothing

When pump is predicted broken:

1. Send a script to SCADA/HMI that will trigger an alert.
2. Manually do these:
 - a. **Check Power Supply and Wiring:** Ensure the pump has a stable power supply and check for loose or damaged wiring, as electrical issues are often the cause of starting failures or inconsistent performance.
 - b. **Inspect for Blockages and Clogs:** Debris buildup in pipes or the impeller can reduce efficiency or cause the pump to stop working. Regularly clear any obstructions to maintain smooth operation.
 - c. **Monitor Pressure and Flow:** Low pressure or erratic water flow can indicate issues such as leaks, worn-out parts, or a malfunctioning pressure switch, all of which should be addressed promptly.
 - d. **Last action:** Prepare to replace it with a new pump.
